# Game rules

The Morris Game, Variant , is a variant of Nine Men's Morris game. It is a board game between two players: White and Black. Each player has 8 pieces, and the game board is as shown above. Pieces can be placed on intersections of lines. (There are a total of 18 locations for pieces.) The goal is to capture opponents pieces by getting three pieces on a single line (a mill). The winner is the first player to reduce the opponent to only 2 pieces, or block the opponent from any further moves. The game has three distinct phases: opening, midgame, and endgame.

**Opening:** Players take turns placing their 8 pieces - one at a time - on any vacant board intersection spot.

Midgame: Players take turns moving one piece along a board line to any adjacent vacant spot.

**Endgame:** A player down to only three pieces may move a piece to any open spot, not just an adjacent one (hopping).

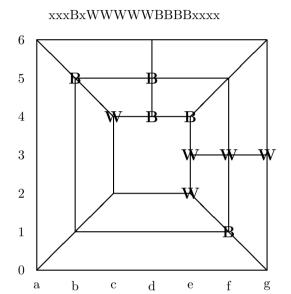

Mills: At any stage if a player gets three of their pieces on the same straight board line (a mill), then one of the opponent's isolated pieces is removed from the board. An isolated piece is a piece that is not part of a mill.

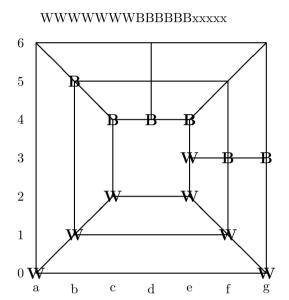

# A computer program that plays Variant

The basic components of a computer program that plays Variant are a procedure that generates moves, a function for assigning a static estimation value for a given position, and a MiniMax or AlphaBeta procedure.

# Representing board positions

One way of representing a board position is by an array of length 18, containing the pieces as the letters W, B, x. (The letter x stands for a "non-piece".) The array specifies the pieces starting from bottom-left and continuing left-right bottom up. Here are a two examples:

# Move generator

A move generator gets as input a board position and returns as output a list of board positions that can be reached from the input position. In the next section we describe a pseudo-code that can be used as a move generator for White. A move generator for Black can be obtained by the following steps.

**Input:** a board position b.

**Output:** a list L of all positions reachable by a black move.

- 1. compute the board tempb by swapping the colors in b. Replace each W by a B, and each B by a W.
- 2. Generate L containing all positions reachable from **tempb** by a white move.
- 3. Swap colors in all board positions in L, replacing W with B and B with W.

#### A move generator for White

A pseudo-code is given for the following move generators: **GenerateAdd**, generates moves created by adding a white piece (to be used in the opening). **GenerateMove**, generates moves created by moving a white piece to an adjacent location (to be used in the midgame). **GenerateHopping**, generates moves created by white pieces hopping (to be used in the endgame). These routines get as an input a board and generate as output a list L containing the generated positions. They require a method of generating moves created by removing a black piece from the board. We name it **GenerateRemove**.

### GenerateMovesOpening

```
Input: a board position
```

Output: a list L of board positions

Return the list produced by **GenerateAdd** applied to the board.

### ${\bf Generate Moves Midgame Endgame}$

```
Input: a board position
```

Output: a list L of board positions

if the board has 3 white pieces Return the list produced by **GenerateHopping** applied to the board. Otherwise return the list produced by **GenerateMove** applied to the board.

#### GenerateAdd

```
Input: a board position
Output: a list L of board positions
L = empty list
for each location in board:
    if board[location] == empty {
        b = copy of board; b[location] = W
        if closeMill(location, b) generateRemove(b, L)
        else add b to L
     }
return L
```

# GenerateHopping

```
Input: a board position

Output: a list L of board positions

L = empty list
for each location \alpha in board
if board[\alpha] == W {
	for each location \beta in board
	if board[\beta] == empty {
	b = copy of board; b[\alpha] = empty; b[\beta] = W
	if closeMill(\beta, b) generateRemove(b, L)
	else add b to L
	}
}
return L
```

#### GenerateMove

```
Input: a board position
Output: a list L of board positions
L = empty list
for each location in board
if board[location]==W {
      n = list of neighbors of location
      for each j in n
      if board[j] == empty {
           b = copy of board; b[location] = empty; b[j]=W
           if closeMill(j, b) GenerateRemove(b, L)
           else add b to L
      }
return L
GenerateRemove
Input: a board position and a list L
Output: positions are added to L by removing black pieces
for each location in board:
      if board[location]==B {
      if not closeMill(location, board) {
           b = copy of board; b[location] = empty
           add b to L
      } }
If no positions were added (all black pieces are in mills) add the input board
     position to L.
```

### neighbors and closeMill

The proposed coding of the methods neighbors and closeMill is by "brute force". The idea is as follows.

#### neighbors

```
Input: a location j in the array representing the board Output: a list of locations in the array corresponding to j's neighbors switch(j) { case j==0\ (a0): return\ [1,2,15]. (These are g0,b1,a6.) case <math>j==1\ (g0): return\ [0,3,11]. (These are a0,f1,g3.) etc. }
```

#### closeMill

```
Input: a location j in the array representing the board and the board b Output: true if the move to j closes a mill C = b[j]; C \text{ must be either W or B. Cannot be x.} switch(j) { case \ j{=}=0 \ (a0): return \ true \ if \\ (b[2]{=}{=}C \ and \ b[4]{=}{=}C) \ \{ \ the \ mill \ is \ a0, \ b1, \ c2 \ \} else return false case \ j{=}=1 \ (g0): return \ true \ if \\ (b[3]{=}{=}C \ and \ b[5]{=}{=}C) \ \{ \ the \ mill \ is \ g0, \ f1, \ e2 \ \} or (b[11]{=}{=}C \ and \ b[20]{=}{=}C) \ \{ \ the \ mill \ is \ g0, \ g3, \ g6 \ \} else return false etc. \}
```

# Static estimation

The following static estimation functions are proposed. Given a board position b compute:  $\mathbf{numWhitePieces} = \mathbf{the}$  number of white pieces in b.  $\mathbf{numBlackPieces} = \mathbf{the}$  number of black pieces in b.  $L = \mathbf{the}$  MidgameEndgame positions generated from b by a black move.  $\mathbf{numBlackMoves} = \mathbf{the}$  number of board positions in L.

# A static estimation for MidgameEndgame:

```
if (numBlackPieces \le 2) return(10000) else if (numWhitePieces \le 2) return(-10000) else if (numBlackMoves==0) return(10000) else return (1000(numWhitePieces - numBlackPieces) - numBlackMoves)
```

#### A static estimation for Opening:

return (numWhitePieces - numBlackPieces)
